

Amendments to the Claims:

This listing of claims replaces all prior versions and listings of claims in the application:

Listing of Claims:

1. (Original) In a computer program, a method for maintaining dependencies among a set of objects each having a value, the set of objects including an object A and an object B, the method for maintaining dependencies comprising:

when the value of object A is a function of the value of object B and the value of object B changes, marking object A as dirty and not recomputing the value of object A until object A is queried for a value;

A/ when the value of object B changes, invalidating the dependents of object B and all of their further dependents, including severing dependencies among the dependents of object B and all of their further dependents; and

causing each invalidated observer-only object to recompute its value by querying the values of the objects from which the observer-only object depends.

2. (Original) The method of claim 1, further comprising:

providing object B in the construction of object A, wherein the value of object A is a function of the value of the object B that was provided in the construction of object A.

3. (Original) The method of claim 1, further comprising:

providing in object B a handleRequest method that adds a requester owned by object A to a dependents list for object B, the dependents list identifying all objects whose value is a function of the value of object B.

4. (Original) The method of claim 3, wherein the dependents lists for all objects in the set collectively define a directed, acyclic dependency graph.

5. (Original) The method of claim 1, further comprising:
when an object is marked as dirty, breaking any dependency relationships the marked object may have had; and
when the value of an object is recomputed, identifying the objects on which the recomputed value is actually dependent and identifying the recomputed object as dependent only on the identified objects.
6. (Original) The method of claim 1, wherein the set of objects includes settable objects and dependent objects, and each dependent object maintains a flag whose setting marks the dependent object as valid or invalid (i.e., dirty).
-  7. (Original) In a computer program, a method for maintaining dependencies among a set of objects each having a value, the method for maintaining dependencies comprising:
identifying the objects upon which a given object depends as those objects into which the given object passed itself as a requester during execution of a compute method of the given object; and
marking the given object as dirty whenever the value of any one of the identified objects changes and not recomputing the value of the given object until the given object is queried for a value.
8. (Original) The method of claim 7, further comprising:
identifying as dependents of a root object all objects that passed themselves as requester objects to the root object or to a dependent of the root object during execution of the requester objects' respective compute methods, whereby the set of dependents of the root object is a set that changes based on the computation of dependents and not the root object itself.
9. (Original) The method of claim 7, wherein the set of objects includes settable objects and dependent objects, and each dependent object maintains a flag whose setting marks the dependent object as valid or invalid (i.e., dirty).

10. (Canceled) A method for making an operation in a computer program application consistent, the operation comprising one or more queries for values of one or more objects having values, each query operating to read the value of an object, the method comprising:
using a requester object to make each of the operation's queries;
establishing a requester-object relationship with each object whose value is available to be queried by the operation; and
if the value of any of the one or more objects is unavailable to be read by the operation, then interrupting the operation, terminating all of the operation's requester-object relationships, and then retrying the operation.

11. (Currently amended) A method for changing objects having values defining state of a computer program application, comprising:
receiving a change to a value of a changed object, the changed object being a settable object in the computer program application;
registering the change with a transaction;
dirtying all objects dependent (directly or indirectly) on the changed object;
severing dependencies from the changed object and all of its direct and indirect dependent objects; and
whenever a leaf object is encountered as a dependent object, enqueueing the leaf object for synchronization after the transaction is committed.

12. (Canceled) The method of claim 11, further comprising:
severing dependencies from the changed object and all of its direct and indirect dependent objects.

13. (Original) The method of claim 11, wherein leaf object synchronization comprises:
recomputing a value for each objects marked as dirty, identifying the objects on which the recomputed value is actually dependent, and identifying the recomputed object as dependent only on the identified objects.

14. (Original) The method of claim 13, further comprising:

using a requester object to make the transaction consistent, the requester object operating to request an object's value so that the requested value cannot change until the requester terminates, at which time all objects whose values were requested by the requester object are released.

15. (Original) A method for changing objects defining state of a computer program application, comprising:

creating a transaction registering with the transaction one or more changes to settable objects, each change being made to a corresponding changing object;

for each change registered, traversing a dependency graph from the changing object and

(i) for each dependent object on the dependency graph, marking the dependent object as dirty and detaching the dependent object from the dependency graph, and (ii) accumulating each leaf object encountered in traversing the dependency graph in a strobe queue; and

traversing the strobe queue after all changes to settable objects have been registered and synchronizing each leaf object by recomputing values for objects marked as dirty and rejoining recomputed objects with the dependency graph, whereby leaf objects are rejoined with the dependency graph.

16. (Original) The method of claim 15, wherein:

the dependency graph represents application state;

the roots of the dependency graph are the settable objects of the application state; and

the intermediate nodes of the dependency graph are dependent objects whose values are the results of intermediate computations.

17. (Original) The method of claim 15, wherein:

the leaf objects of the dependency graph are coupled to a user interface.

18. (Original) The method of claim 17, wherein:

the leaf objects are coupled directly to the user interface.

19. (Original) In a computer program, a method for managing dependency among a set of objects, each object of the set having a value, the set including dependent objects, each dependent object having a value that is a function of the values of one or more of the other objects in the set, the method comprising:

calculating the dependency among objects in the set dynamically at the time objects calculate their values.

20. (Currently amended) The method of claim 19, wherein each observed object in the set has one or more accessor methods that each take [[an]] a requester argument and returns a current value of the observed object; the requester argument identifying the object requesting the value of the observed object.

21. (Currently amended) The method of claim 19, wherein each settable object in the set has [[an]] a value-setting method that takes two arguments, namely a transaction argument identifying a transaction with which the change to the settable object's value is registered and a new value for the settable object.

22. (Original) The method of claim 19, wherein:
each object in the set descends from a VValue class;
each computation operation is represented by a Requester object that is owned by a dependent VValue object, and the Requester object enters the dependent set of one or more VValue objects from which the dependent VValue object depends; and
the dependent object uses the Requester object to obtain the object values the dependent object needs to calculate its own value.

23. (Original) The method of claim 22, wherein a Transaction class descends from the Requester class, the method further comprising:
accumulating changes to one or more settable VValue objects in a Transaction object;
and
executing the Transaction object.

24. (Canceled) A method for providing a dependency management system for managing application state in a consistent manner, comprising:
providing a VValue class for objects having values representing application state; and
providing in VValue objects a handleRequest method that, when executed, causes an object A to be identified in a dependents list for an object B, the dependents list identifying all objects whose value is a function of the value of VValue object B.

 25. (Canceled) The method of claim 24, wherein:
the method further comprises providing a Requester class, a Requester object being operable to guarantee consistency in values queried from VValue objects by locking requested VValue values until an operation invoking the Requester object terminates; and
the handleRequest method takes as an argument a Requester A owned by the object A and causes the Requester A to be added to the dependents list for the object B, the dependents list containing Requesters owned by all objects whose value is a function of the value of the object B.

26. (Canceled) The method of claim 24, wherein the dependency management system is transaction-based.

27. (Canceled) The method of claim 24, wherein the dependency management system is threadsafe.

28. (Original) A system for maintaining dependencies among a set of objects in a computer program, each object having a value, the set of objects including an object A and an object B, the system comprising:

means for recomputing the value of object A, wherein when the value of object A is a function of the value of object B and the value of object B changes, marking object A as dirty and not recomputing the value of object A until object A is queried for a value;

means for recomputing the value of object B, wherein when the value of object B changes, invalidating the dependents of object B and all of their further dependents, including severing dependencies among the dependents of object B and all of their further dependents; and

means for causing each invalidated observer-only object to recompute its value by querying the values of the objects from which the observer-only object depends.

AM
CMT
29. (Original) A system for maintaining dependencies among a set of objects in a computer program, each object having a value, the system comprising:

means for identifying the objects upon which a given object depends as those objects into which the given object passed itself as a requester during execution of a compute method of the given object; and

means for marking the given object as dirty whenever the value of any one of the identified objects changes and not recomputing the value of the given object until the given object is queried for a value.

30. (Canceled) A system for making an operation in a computer program application consistent, the operation comprising one or more queries for values of one or more objects having values, each query operating to read the value of an object, the system comprising:

means for using a requester object to make each of the operation's queries; and

means for establishing a requester-object relationship with each object whose value is available to be queried by the operation; wherein

if the value of any of the one or more objects is unavailable to be read by the operation, then interrupting the operation, terminating all of the operation's requester-object relationships, and then retrying the operation.

31. (Currently amended) A system for changing objects having values defining state of a computer program application, comprising:

means for receiving a change to a value of a changed object, the changed object being a settable object in the computer program application;

means for registering the change with a transaction; [[and]]

means for dirtying all objects dependent (directly or indirectly) on the changed object;

and

means for severing dependencies from the changed object and all of its direct and indirect dependent objects; wherein

whenever a leaf object is encountered as a dependent object, the leaf object is enqueued for synchronization after the transaction is committed.

32. (Original) A system for changing objects defining state of a computer program application, comprising:

means for creating a transaction registering with the transaction one or more changes to settable objects, each change being made to a corresponding changing object;

means for traversing a dependency graph, for each change registered, from the changing object and (i) for each dependent object on the dependency graph, marking the dependent object as dirty and detaching the dependent object from the dependency graph, and (ii) accumulating each leaf object encountered in traversing the dependency graph in a strobe queue; and

means for traversing the strobe queue after all changes to settable objects have been registered and synchronizing each leaf object by recomputing values for objects marked as dirty and rejoining recomputed objects with the dependency graph, whereby leaf objects are rejoined with the dependency graph.

33. (Original) A system for managing dependency among a set of objects in a computer program, each object of the set having a value, the set including dependent objects, each dependent object having a value that is a function of the values of one or more of the other objects in the set, the system comprising:

means for determining a time at which objects calculate their values; and
means for calculating the dependency among objects in the set dynamically at the time objects calculate their values.

34. (Canceled) A system for providing a dependency management system for managing application state in a consistent manner, comprising:

means for providing a VValue class for objects having values representing application state; and

means for providing in VValue objects a handleRequest method that, when executed, causes an object A to be identified in a dependents list for an object B, the dependents list identifying all objects whose value is a function of the value of VValue object B.

 35. (Original) A computer program product, tangibly stored on a computer-readable medium, for maintaining dependencies among a set of objects each having a value, the set of objects including an object A and an object B, the product comprising instructions operable to cause a computer to:

recompute the value of object A, wherein when the value of object A is a function of the value of object B and the value of object B changes, object A is marked as dirty and the value of object A is not recomputed until object A is queried for a value;

recompute the value of object B, wherein when the value of object B changes, the dependents of object B and all of their further dependents are invalidated, and the dependencies among the dependents of object B and all of their further dependents are severed; and

cause each invalidated observer-only object to recompute its value by querying the values of the objects from which the observer-only object depends.

36. (Original) A computer program product, tangibly stored on a computer-readable medium, for maintaining dependencies among a set of objects in a computer program, each object having a value, the product comprising instructions operable to cause a computer to:

identify the objects upon which a given object depends as those objects into which the given object passed itself as a requester during execution of a compute method of the given object; and

mark the given object as dirty whenever the value of any one of the identified objects changes and not recompute the value of the given object until the given object is queried for a value.

37. (Canceled) A computer program product, tangibly stored on a computer-readable medium, for making an operation in a computer program application consistent, the operation comprising one or more queries for values of one or more objects having values, each query operating to read the value of an object, the product comprising instructions operable to cause a computer to:

use a requester object to make each of the operation's queries;

establish a requester-object relationship with each object whose value is available to be queried by the operation; and

interrupt the operation if the value of any of the one or more objects is unavailable to be read by the operation, terminating all of the operation's requester-object relationships, and then retry the operation.

38. (Currently amended) A computer program product, tangibly stored on a computer-readable medium, for changing objects having values defining state of a computer program application, the product comprising instructions operable to cause a computer to:

receive a change to a value of a changed object, the changed object being a settable object in the computer program application;

register the change with a transaction;

dirty all objects dependent (directly or indirectly) on the changed object;

sever dependencies from the changed object and all of its direct and indirect dependent objects; and

whenever a leaf object is encountered as a dependent object, enqueue the leaf object for synchronization after the transaction is committed.

39. (Original) A computer program product, tangibly stored on a computer-readable medium, for changing objects defining state of a computer program application, the product comprising instructions operable to cause a computer to:

create a transaction registering with the transaction one or more changes to settable objects, each change being made to a corresponding changing object;

traverse a dependency graph, for each change registered, from the changing object and (i) for each dependent object on the dependency graph, marking the dependent object as dirty and detaching the dependent object from the dependency graph, and (ii) accumulating each leaf object encountered in traversing the dependency graph in a strobe queue; and

traverse the strobe queue after all changes to settable objects have been registered and synchronizing each leaf object by recomputing values for objects marked as dirty and rejoining recomputed objects with the dependency graph, whereby leaf objects are rejoined with the dependency graph.

40. (Original) A computer program product, tangibly stored on a computer-readable medium, for managing dependency among a set of objects in a computer program, each object of the set having a value, the set including dependent objects, each dependent object having a value that is a function of the values of one or more of the other objects in the set, the product comprising instructions operable to cause a computer to:

calculate the dependency among objects in the set dynamically at the time objects calculate their values.

41. (Canceled) A computer program product, tangibly stored on a computer-readable medium, for providing a dependency management system for managing application state in a consistent manner, the product comprising instructions operable to cause a computer to:

provide a VValue class for objects having values representing application state; and
provide in VValue objects a handleRequest method that, when executed, causes an object A to be identified in a dependents list for an object B, the dependents list identifying all objects whose value is a function of the value of VValue object B.

42. (New) The product of claim 35, further comprising instructions operable to:
provide object B in the construction of object A, wherein the value of object A is a
function of the value of the object B that was provided in the construction of object A.
43. (New) The product of claim 35, further comprising instructions operable to:
provide in object B a handleRequest method that adds a requester owned by object A to a
dependents list for object B, the dependents list identifying all objects whose value is a function
of the value of object B.
44. (New) The product of claim 43, wherein the dependents lists for all objects in the set
collectively define a directed, acyclic dependency graph.
45. (New) The product of claim 35, further comprising instructions operable to:
break any dependency relationships the marked object may have had when an object is
marked as dirty; and
when the value of an object is recomputed, identify the objects on which the recomputed
value is actually dependent and identify the recomputed object as dependent only on the
identified objects.
46. (New) The product of claim 35, wherein the set of objects includes settable objects and
dependent objects, and each dependent object maintains a flag whose setting marks the
dependent object as valid or invalid (i.e., dirty).
47. (New) The product of claim 36, further comprising instructions operable to:
identify as dependents of a root object all objects that passed themselves as requester
objects to the root object or to a dependent of the root object during execution of the requester
objects' respective compute methods, whereby the set of dependents of the root object is a set
that changes based on the computation of dependents and not the root object itself.

48. (New) The product of claim 36, wherein the set of objects includes settable objects and dependent objects, and each dependent object maintains a flag whose setting marks the dependent object as valid or invalid (i.e., dirty).

49. (New) The product of claim 38, wherein leaf object synchronization comprises:
recomputing a value for each objects marked as dirty, identifying the objects on which the recomputed value is actually dependent, and identifying the recomputed object as dependent only on the identified objects.

50. (New) The product of claim 38, further comprising instructions operable to:
use a requester object to make the transaction consistent, the requester object operating to request an object's value so that the requested value cannot change until the requester terminates, at which time all objects whose values were requested by the requester object are released.

51. (New) The product of claim 39, wherein:
the dependency graph represents application state;
the roots of the dependency graph are the settable objects of the application state; and
the intermediate nodes of the dependency graph are dependent objects whose values are the results of intermediate computations.

52. (New) The product of claim 39, wherein:
the leaf objects of the dependency graph are coupled to a user interface.

53. (New) The product of claim 52, wherein:
the leaf objects are coupled directly to the user interface.

54. (New) The product of claim 40, wherein each observed object in the set has one or more accessor methods that each take a requester argument and returns a current value of the observed object, the requester argument identifying the object requesting the value of the observed object.

55. (New) The product of claim 40, wherein each settable object in the set has a value-setting method that takes two arguments, namely a transaction argument identifying a transaction with which the change to the settable object's value is registered and a new value for the settable object.

56. (New) The product of claim 40, wherein:

each object in the set descends from a VValue class;

each computation operation is represented by a Requester object that is owned by a dependent VValue object, and the Requester object enters the dependent set of one or more VValue objects from which the dependent VValue object depends; and

the dependent object uses the Requester object to obtain the object values the dependent object needs to calculate its own value.

57. (New) The product of claim 56, wherein a Transaction class descends from the Requester class, the product further comprising instructions operable to:

accumulate changes to one or more settable VValue objects in a Transaction object; and
execute the Transaction object.
